

- **The MC9S12 A/D Converter**
  - Introduction to A/D Converters
  - Single Channel vs Multiple Channels
  - Single Conversion vs Multiple Conversions
  - MC9S12 A/C Registers
  - Using the MC9S12 A/D Converter
  - A C program to use the MC9S12 A/D Converter

## **Analog to Digital Converters (A/D)**

- An Analog-to-Digital (A/D) converter converts an analog voltage into a digital number
- There are a wide variety of methods used for A/D converters  
Examples are:
  - Flash (Parallel)
  - Successive Approximation
  - Sigma-Delta
  - Dual Slope Converter
- A/D converters are classified according to several characteristics
  - Resolution (number of bits) — **typically 8 bits to 24 bits**
  - Speed (number of samples per second) — several samples/sec to several billion samples/sec
  - Accuracy — how much error there is in the conversion.
- High-resolution converters are usually slower than low-resolution converters
- The MC9S12 has two 10-bit successive approximation A/D converters (which can be used in 8-bit mode)
- The MC9S12 uses an analog multiplexer to allow eight input pins to connect to any of the A/D converters.

## Comparator

- A comparator is used in many types of A/D converters.
- A comparator is the simplest interface from an analog signal to a digital signal
- A comparator compares two voltage values on its two inputs:

If the voltage on the + input is greater than the voltage on the - input, the output will be a logic high

If the voltage on the + input is less than the voltage on the - input, the output will be a logic low

**If  $V_{in} > V_{ref}$  then  $V_{out} = V_{cc}$**

**If  $V_{in} < V_{ref}$  then  $V_{out} = 0$**

## Flash (Parallel) A/D Converter

- A flash A/D converter is the simplest to understand
- A flash A/D converter compares an input voltage to a large number of reference voltages
- An n-bit flash converter uses  $2^n - 1$  comparators
- The output of the A/D converter is determined by which of the two reference voltages the input signal is in between

### **Flash (Parallel) A/D Converter**

- A B-bit Flash A/D converter requires  $2^B - 1$  comparators
- An 8-bit Flash A/D requires 255 comparators
- A 12-bit Flash A/D converter would require 4,095 comparators!
  - Cannot integrate 4,095 comparators onto an IC
- Such A/D are available in IC from up to 8-bit and 10-bit
- Flash A/D converters can sample at several billion samples/sec

### **A/D Converter Resolution and Quantization**

- If the voltage input voltage is 3.2516 V, the lowest 5 comparators will be turned on, and the highest 2 comparators will be turned off
- The output of the 3-bit flash A/D converter will be 5 (101)
- For a 3-bit A/D converter, which has a range from 0 to 5 V, an output of 5 indicates that the input voltage is between 3.125 V and 3.750 V
- A 3-bit A/D converter with a 5 V input range has a quantization value of 0.625 V
- The quantization value of an A/D converter can be found by

$$\Delta V = (V_{RH} - V_{RL})/2^b$$

where  $V_{RH}$  is the highest voltage the A/D converter can handle,  $V_{RL}$  is the lowest voltage the A/D converter can handle, and  $b$  is the number of bits of the A/D converter

- The HC12 has a 10-bit A/D converter. The typical voltage range used for the HC12 A/D is  $V_{RH} = 5 \text{ V}$  and  $V_{RL} = 0 \text{ V}$ , so the HC12 has a quantization value of

$$\Delta V = (5 \text{ V} - 0 \text{ V})/2^{10} = 4.88 \text{ mV}$$

- The dynamic range of an A/D converter is given in decibels (dB):

$$\text{DR(dB)} = 20 \log 2^b = 20 b \log(2) = 6.02b$$

- A 10-bit A/D converter has a dynamic range of

$$\text{DR(dB)} = 6.02 \times 10 = 60.2 \text{ dB}$$

## A/D Sampling Rate

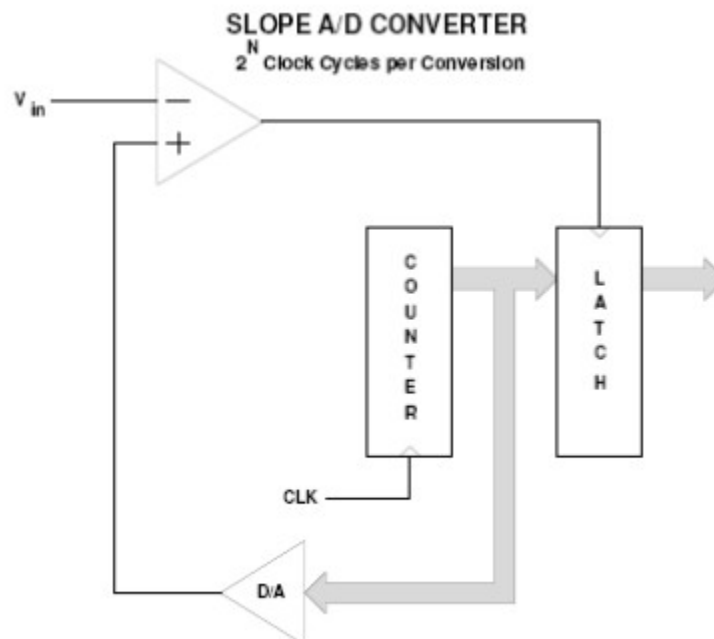

- The rate at which you sample a signal depends on how rapidly the signal is changing
- If you sample a signal too slowly, the information about the signal may be inaccurate.

- A 1,050 Hz signal sampled at 500 Hz looks like a 50 Hz signal
- To get full information about a signal you must sample more than twice the highest frequency in the signal. (Nyquist theorem).
- Practical systems typically use a sampling rate of at least four times the highest frequency in the signal.

## Slope A/D Converter

- A simple A/D converter can be constructed with a counter and a D/A converter
- The counter counts from 0 to  $2^b - 1$
- The counter drives the input of the D/A converter
- The output of the D/A converter is compared to the input voltage
- When the output of the comparator switches logic level, the generated voltage passed the input voltage
- By latching the output of the counter at this time, the input voltage can be determined (with the accuracy of the quantization value of the converter)
- Problem with Slope A/D converter: Could take  $2^b$  clock cycles to test possible values of reference voltages

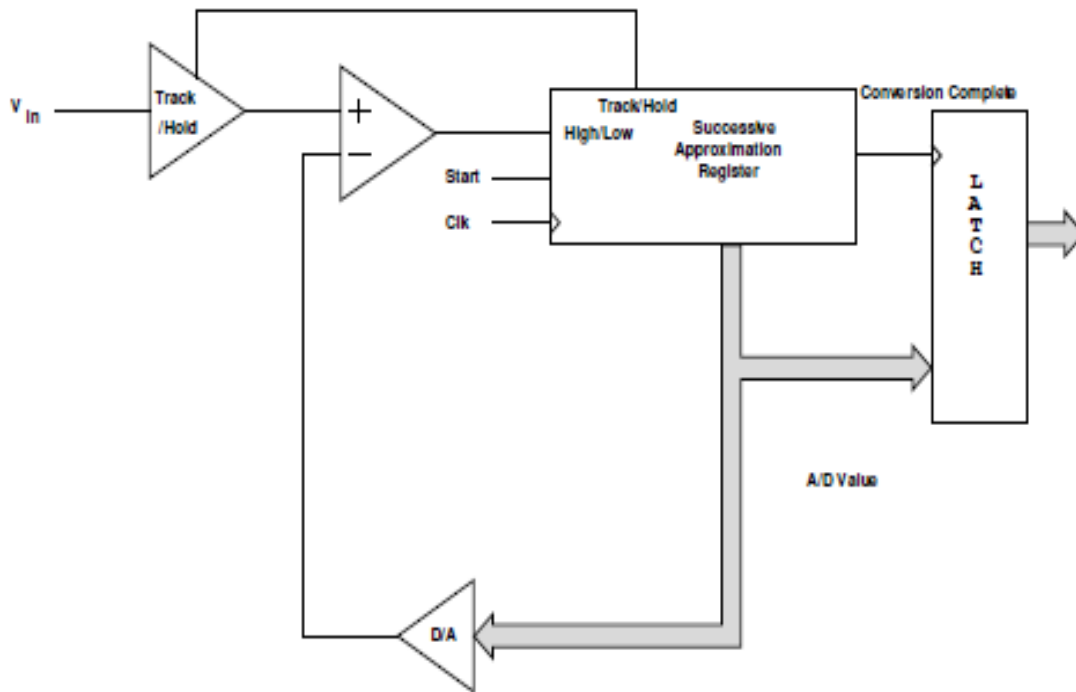

### **Successive Approximation A/D Converter**

- A successive approximation (SA) A/D converter **uses an intelligent scheme** to determine the input voltage
- It first tries a voltage half way between  $V_{RH}$  and  $V_{RL}$
- It determines if the signal is in the **lower half** or the **upper half** of the voltage range
  - If the input is in the upper half of the range, it sets the most significant bit of the output
  - If the input is in the lower half of the range, it clears the most significant bit of the output

- The first clock cycle eliminates half of the possible values
- On the next clock cycle, the SA A/D tries a voltage in the middle of the remaining possible values
- The second clock cycle allows the SA A/D converter to determine the second most significant bit of the result
- For a B-bit SA A/D converter, it takes B clock cycles to determine the value of the input voltage
- An SA A/D converter can give the wrong output if the voltage changes during a conversion
- An SA A/D converter **needs an input buffer** which holds the input voltage constant during the conversion
- This input buffer is called a **Track/Hold** or **Sample/Hold** circuit
- It usually works by charging a capacitor to the input voltage, then disconnecting the capacitor from the input voltage during conversion
- The voltage on the capacitor remains constant during conversion
- The HC12 has a Track/Hold amplifier built in
- SA A/D converters have resolutions of up to 16 bits
- SA A/D converters have speeds up to several million samples per second

**SUCCESSIVE APPROXIMATION A/D CONVERTER**

## **MC9S12 Analog/Digital Converter**

- A 10-bit A/D converter is used to convert an input voltage. The reference voltages are  $V_{RL} = 0V$  and  $V_{RH} = 5V$ .

– What is the quantization level of the A/D converter?

$$\Delta V = (V_{RH} - V_{RL}) / (2^b - 1) = 4.88 \text{ mV}$$

- If the value read from the A/D converter is 0x15A, what is the input voltage?

$$V_{in} = V_{RL} + [(V_{RH} - V_{RL}) / (2^b - 1)] * ADvalue = 0 \text{ V} + 4.88 \text{ mV} \times 346 = 1.6894 \text{ V}$$

- The MC9S12 has two 10-bit A/D converters (ATD0 and ATD1).

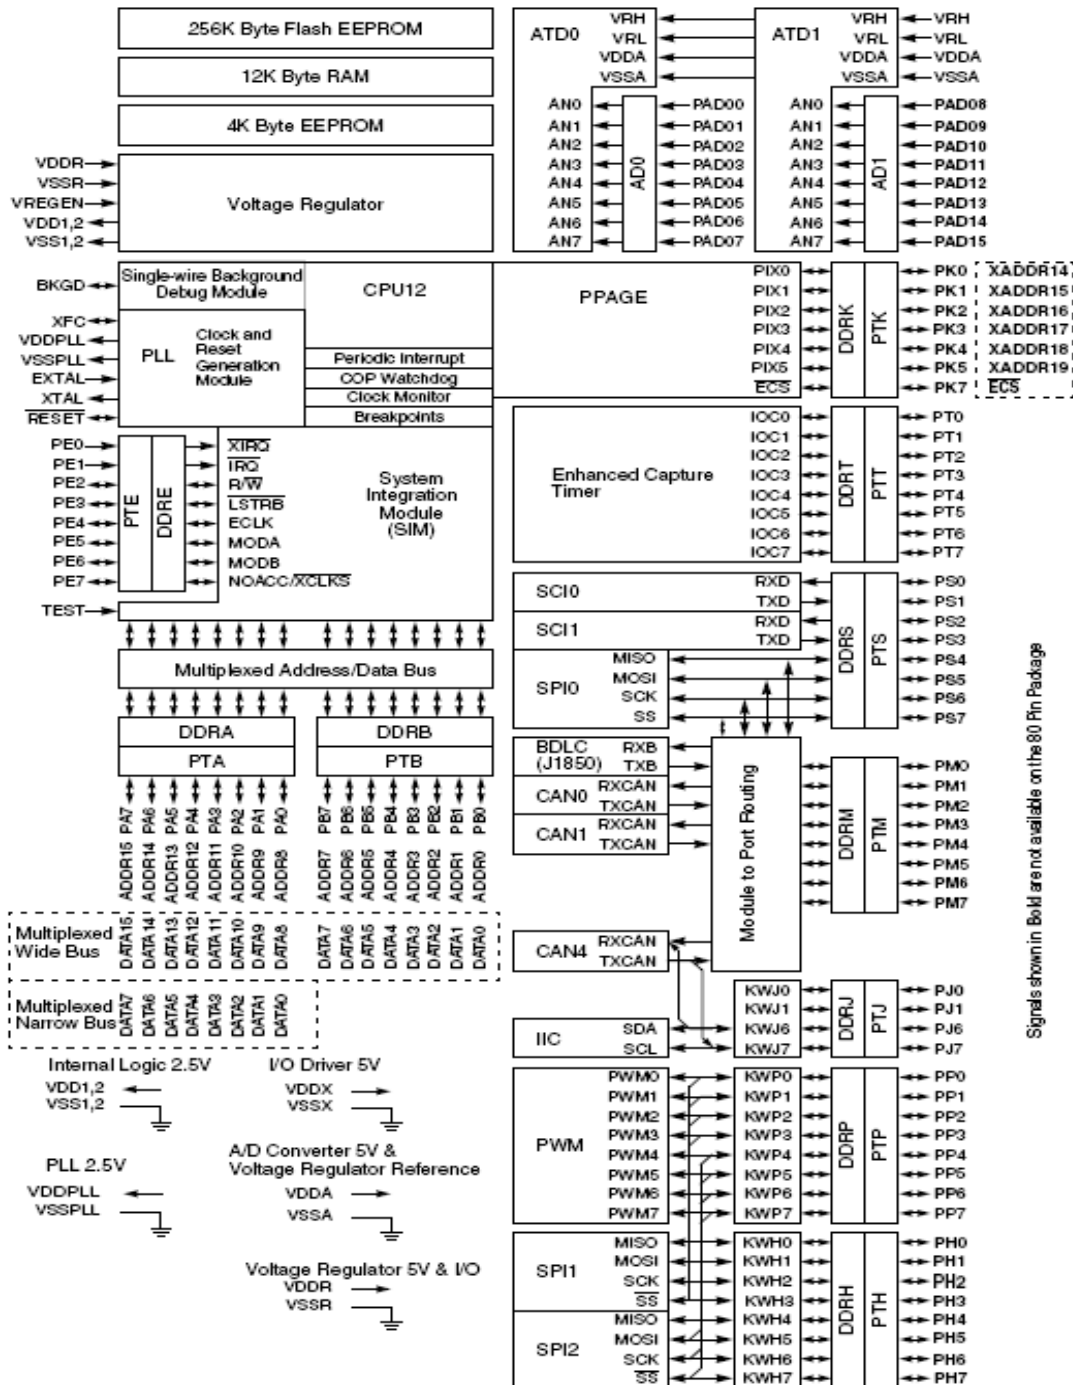

-Each A/D converter has an 8-channel analog multiplexer in front of it, so each channel can convert 8 analog inputs (but not at exactly the same time).

- ATD0 uses the eight bits of Port AD0, called PAD00 through PAD07

-PAD00 and PAD01 of ATD0 are used by DBug-12 at startup to determine whether to execute DBug-12, or to run code from EEPROM of the bootloader.

- ATD1 uses the eight bits of Port AD1, called PAD08 through PAD15

**Figure 1-1 MC9S12DT256 Block Diagram**

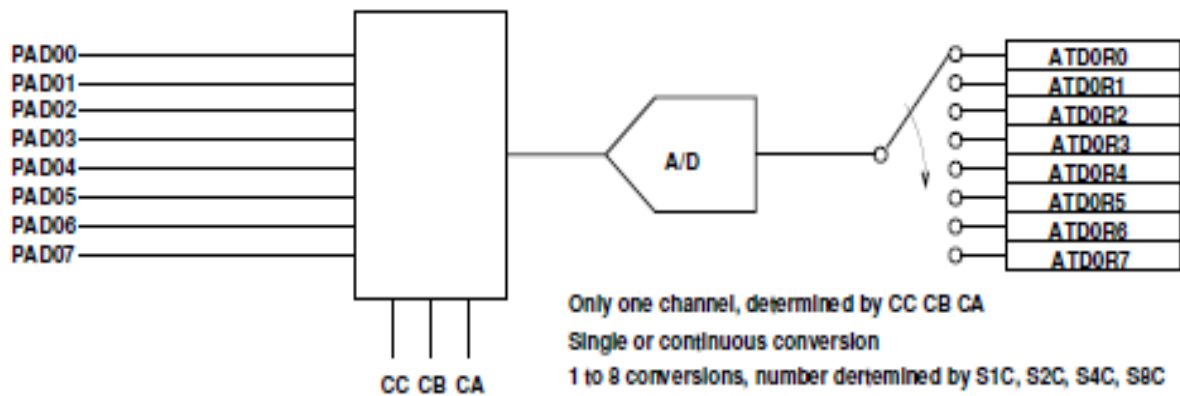

## **The MC9S12 Analog/Digital Converter**

- We will discuss only ATD0. ATD1 is identical.
- ATD0 is an eight-channel 10-bit A/D converter.
  - The A/D converter can also be used in 8-bit mode.
- There are eight inputs to the A/D converter.
- The inputs are fed through a multiplexer to the single A/D converter.
- There are inputs on the HCS12 for the reference voltages  $V_{RL}$  and  $V_{RH}$ 
  - In normal operation  $V_{RL} = 0\text{ V}$  and  $V_{RH} = 5\text{ V}$ .
  - You must have  $V_{SS} \leq V_{RL} < V_{RH} \leq V_{DD}$ .
  - The accuracy of the A/D converter is guaranteed only for  $V_{RH} - V_{RL} = 5\text{ V}$ .
- When using the A/D converter, you can choose between performing single or continuous conversion on a single channel, or multiple channels.
- The AD conversion results are stored in the registers ATD0DR0 through ATD0DR7
  - You can choose whether to have the results left-justified or right justified.

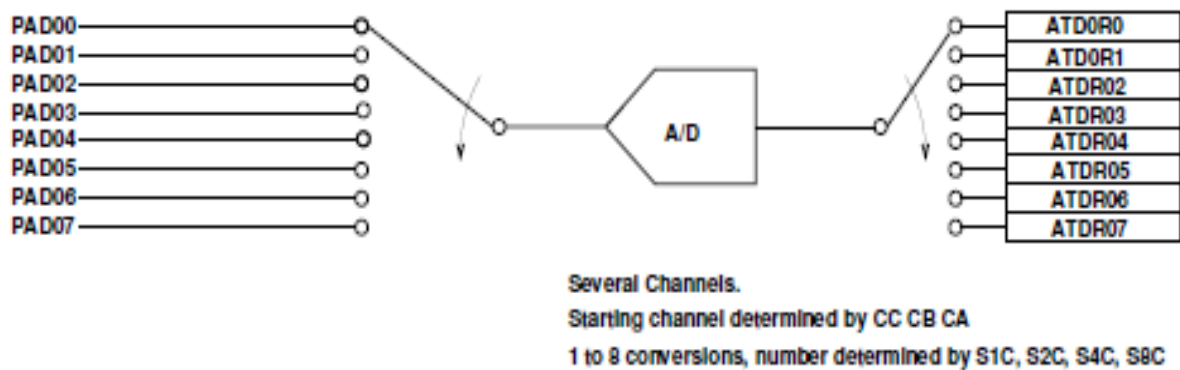

- To program the HCS12 A/D converter you need to set up the A/D control registers **ATD0CTL2, ATD0CTL3, ATD0CTL4 and ATD0CTL5.**
- The registers ATD0CTL0 and ATD0CTL1 are used for factory test, and not used in normal operation.
- When the AD converter is not used, Port AD0 can be used for a general purpose input (not as a GPIO – General Purpose I/O like the other ports).
  - Register ATD0DIEN is used to set up Port AD0 pins for use as a general purpose inputs.
  - The values on the pins are read from PORTAD0.

### To Use A/D Converter:

ADPU = 1 (Power up A/D)

SCAN = 0 => Single conversion sequence

SCAN = 1 => Convert continuously

S8C, S4C, S2C, S1C:

Number of conversions per sequence: 0001 -- 0111 (1 to 7)

0000 or 1xxx (8)

SRES8 = 0 => 10 Bit Mode

SRES8 = 1 => 8 Bit Mode

DJM = 0 => Left justified data in the result registers

DJM = 1 => Right justified data in the result registers

DSGN = 0 => Unsigned data in the result registers

DSGN = 1 => Signed data representation in the result registers  
(only for left justified)

ATDCTL4= 0x85 => 2 MHz AD clock, 12 cycles per conversion,  
8 bit mode

ATDCTL4= 0x05 => 2 MHz AD clock, 14 cycles per conversion,  
10 bit mode

-Other values of ATDCTL4 will not work, or will result in  
slower operation of A/D

SCF Flag is set after a sequence of conversions is complete

-The SCF Flag is cleared when ATD0CTL5 is written, or by  
writing a 1 to the SCF bit

After writing to ATD0CTL5, SCF flag cleared and conversions  
start

## **Using the HCS12 A/D converter**

1. Power up A/D Converter (ADPU = 1 in ATD0CTL2)
2. Select number of conversions per sequence (S8C S4C S2C S1C in ATD0CTL3)

S8C S4C S2C S1C = 0001 to 0111 for 1 to 7 conversions

S8C S4C S2C S1C = 0000 or 1xxx for 8 conversions

3. Set up ATD0CTL4

- For 8-bit mode write 0x85 to ATD0CTL4
- For 10-bit mode write 0x05 to ATD0CTL4
- Other values of ATD0CTL4 either will not work or will result in slower A/D conversion rates

4. Select DJM in ATD0CTL5

- (a) DJM = 0 => Left justified data in the result registers
- (b) DJM = 1 => Right justified data in the result registers

5. Select DSGN in ATD0CTL5

- (a) DSGN = 0 => Unsigned data representation in the result register
- (b) DSGN = 1 => Signed data representation in the result register

The Available Result Data Formats are shown in the following table:

<b>SRES8</b>	<b>DJM</b>	<b>DSGN</b>	<b>RESULT DATA FORMAT</b>
1	0	0	8-bit/left justified/unsigned – Bits 15-8
1	0	1	8-bit/left justified/signed – Bits 15-8
1	1	X	8-bit/right justified/unsigned – Bits 7-0
0	0	0	10-bit/left justified/unsigned – Bits 15-6
0	0	1	10-bit/left justified/signed – Bits 15-6
0	1	X	10-bit/right justified/unsigned – Bits 9-0

6. Select MULT in ATD0CTL5:

- MULT = 0: Convert one channel the specified number of times  
– Choose channel to convert with CC, CB, CA of ATD0CTL5.
- MULT = 1: Convert across several channels. CC, CB, CA of ATD0CTL is the first channel to be converted.

7. Select SCAN in ATD0CTL5:

- SCAN = 0: Convert one sequence, then stop
- SCAN = 1: Convert continuously

8. After writing to ATD0CTL5, the A/D converter starts, and the SCF bit is cleared. After a sequence of conversions is completed, the SCF flag in ATD0STAT0 is set.

- You can read the results in ATD0DRxH.

9. If  $SCAN = 0$ , you need to write to  $ATD0CTL5$  to start a new sequence. If  $SCAN = 1$ , the conversions continue automatically, and you can read new values in  $ATD0DRxH$ .

10. To get an interrupt after the sequence of conversions are completed, set  $ASCIE$  bit of  $ATD0CTL2$ . After the sequence of conversions, the  $ASCIF$  bit in  $ATD0CTL2$  will be set, and an interrupt will be generated.

11. With 24 MHz bus clock and  $ATD0CTL4 = 0x05$ , it takes 7  $\mu s$  to make one conversion, 56  $\mu s$  to make eight conversions.

12. On MC9S12 EVBU, AD0 channels 0 and 1 are used to determine start-up program (D-Bug12, EEPROM or bootloader). Do not use AD0 channels 0 or 1, unless absolutely necessary (if you need more than 14 A/D channels).

13.

$$ATD0DRx = (V_{in} - V_{RL}) / (V_{RH} - V_{RL}) \times 1024$$

Normally,  $V_{RL} = 0 V$ , and  $V_{RH} = 5 V$ , so

$$ATD0DRx = V_{in} / 5 V \times 1024$$

Example:  $ATD0DR0 = 448 \Rightarrow V_{in} = 2.19 V$

14. To use 10-bit result, set  $ATD0CTL4 = 0x05$  (Gives 2 MHz AD clock with 24 MHz bus clock, 10-bit mode).

15. You can get more accuracy by averaging multiple conversions. If you need only one channel, set `MULT = 0`, set `S8C`, `S4C`, `S2C`, `S1C`, bits for eight conversions, then average all eight result registers. The following assumes the data was right justified:

```
int avg;
```

```
avg = (ATD0DR0 + ATD0DR1  
      ATD0DR2 + ATD0DR3  
      ATD0DR4 + ATD0DR5  
      ATD0DR6 + ATD0DR7) >> 3;
```

```
/* Read temperature from PAD4. Turn on heater if temp too low,
turn off heater if temp too high. Heater connected to Bit 0 of Port
A. */
```

```
#include "hcs12.h"
```

```
#define TRUE 1
```

```
#define SET_POINT 72 /* Temp at which to turn heater */
/* on or off */
```

```
